# The effects of international trade on structural change and $\mathrm{CO}_{2}$ emissions 

Michael Hübler* Eduard Bukin ${ }^{\dagger}$ Yuting Xi ${ }^{\ddagger}$

October 13, 2020

#### Abstract

This article introduces a new econometric model with an innovative measure of inter-sectoral structural change. It analyzes structural con-/divergence of intersectoral patterns across countries (North-South or global perspective) influenced by international trade. The analysis applies panel data estimators with different types of fixed-effects to the 2019, 2016 and 2013 releases of the World Input-Output Database (WIOD) covering the periods of time 1995-2009 and 2000-2014. The results show that international trade promotes structural convergence, which is enhanced by sectoral capital use. It seems, however, that in this millennium, structural divergence has been fostered by trade-induced specialization in $\mathrm{CO}_{2}$-intensive production.

Keywords: structural change; international trade; $\mathrm{CO}_{2}$ emissions; macro-econometrics; panel data; WIOD

[^0]
## 1 Introduction

Economic growth, particularly of large emerging economies, such as China or India, not only raises output and income but also $\mathrm{CO}_{2}$ emissions. Because of the resulting contribution to global warming, this effect shall be mitigated. Structural change, i.e., the shift of the economy's sectoral composition, can increase or decrease $\mathrm{CO}_{2}$ emissions. Whereas the effects of international trade on productivity gains, economic growth and international technology diffusion (including energy- and $\mathrm{CO}_{2}$-saving technologies) have been extensively researched ${ }^{\square}$ the effect of international trade on inter-sectoral structural change and the resulting impact on $\mathrm{CO}_{2}$ emissions have been hardly understood.

Empirically, inter-sectoral structural change has significantly contributed to changes in energy use and $\mathrm{CO}_{2}$ emissions ${ }^{2}$ Econometric evidence on the effects of international trade on structural change in general, and with respect to $\mathrm{CO}_{2}$ emissions in particular, however, seems to be widely missing. Some studies examine the role of FDI (foreign direct investment) and the European market integration: In a working paper, Barrios et al. (2002) find convergence of per capita incomes and industry sector structures in the European Union supported by inward FDI. Based on sectoral indices and descriptive statistics on exports, structural similarity and structural change, Crespo \& Fontoura (2007) find similar results.

Against this background, our article tries to fill this research gap by exploring the nexus between international trade and structural change from a conceptual and econometric point of view. It contributes to the literature by describing the economic mechanisms of structural change driven by trade conceptually, by introducing a new econometric model with a new measure of structural change with (North-South) con-/divergence, by studying sectoral $\mathrm{CO}_{2}$ emissions (besides sectoral outputs) and by exploiting the newest version of the large bilateral, bisectoral dataset WIOD (World Input-Output Database ${ }^{3}$ ).

According to the Environmental Kuznets Curve hypothesis, during the course of economic development, the sectoral structure of an economy shifts from agriculture towards (heavy) industries, causing higher emissions. It then shifts further towards advanced knowledge-based industries and services causing lower emissions. Consequently, OECD (Organisation for Economic Co-operation and Development) countries are expected to exhibit sectoral structures that create ceteris paribus lower economy-wide $\mathrm{CO}_{2}$ emissions

[^1]than those of emerging countries at medium stages of development. To examine this economic transition process, we first deploy a North-South setup with OECD and emerging countries and then extend it to all countries covered by the WIOD.

Our article particularly addresses the open question whether exports from an (advanced) economy to another (emerging) economy make the two economies more similar or more different with regard to their sectoral structures and the related $\mathrm{CO}_{2}$ emissions. We dub these two alternatives structural convergence and structural divergence. Assuming that both economies continue their economic growth process and the emerging economies catch up towards the industrialized countries, convergence decreases the average $\mathrm{CO}_{2}$ emissions across sectors, whereas divergence increases them.

Theoretically, the role of international trade in structural change is ambiguous. On the one hand, according to the classic trade theories by Ricardo and Heckscher-Ohlin, different economies concentrate their production and exports on different sectors, resulting in structural divergence. Additionally, Krugman's New Economic Geography predicts agglomeration of economic activities, which supports the emergence of specialization and clustering (Midelfart et al., 2003). Induced and directed technological change Acemoglu, 2002, 2010) may reinforce the sectoral heterogeneity across countries.

On the other hand, when knowledge, or more specifically (energy- and $\mathrm{CO}_{2}$-saving) technologies, spread across borders supported by international trade, the use of similar technologies will result in similar productivities across sectors and similar sectoral structures within economies, resulting in structural convergence. Likewise, intensifying inter-industry trade supports the emergence of similar sectoral structures across trading partners (Midelfart et al., 2003). Eventually, in the theoretical long-run equilibrium of a fully integrated world economy, the sectoral structures will be equalized.

The overview by Herrendorf et al. (2014) (sec. 6.6.1 International Trade) reconciles the view of these two camps by arguing that in a country with high productivity growth, the development of the manufacturing sector share exhibits a hump-shape, while in a country with low productivity growth, it exhibits a downward-sloping shape (Yi \& Zhang, 2010). In accordance with the outcome of the Environmental Kuznets Curve theory, this theory implies that structural con- and divergence are theoretically possible across economies depending on (sectoral) productivity growth and the phase of economic development.

Therefore, it is an empirical question, whether structural con- or divergence dominates on average across economies and sectors or in particular sectors at specific periods of time. Compared with the existing literature, our analysis is to our knowledge the first
study showing econometrically that international trade in general promotes structural convergence. This result opposes the classical Ricardian trade theory and supports the modern view of international trade as a driver of technology diffusion. We also find indication for structural divergence in terms of specialization in more or less $\mathrm{CO}_{2}$-intensive production that began recently in this millennium. This insight is important for policy makers because it points to outsourcing of $\mathrm{CO}_{2}$-intensive production from industrialized to emerging economies, so-called carbon leakage, which undermines climate policy efforts.

The article proceeds as follows. Section 2 derives the conceptual framework, Section 3 describes the data, and Section 4 presents the econometric results; Section 5 discusses the results, and Section 6 concludes. The supplementary online appendix provides further statistics and robustness check results.

## 2 Concept

In this section, we develop the econometric model of structural change driven by international trade and further determinants, first for one economy, then for two economies connected via trade. In the next step, we will discuss the theoretical effects of international trade on structural change and spell out two alternative testable hypotheses for the effect of international trade on structural change.

## Sectoral one-economy model:

In economy $e$ and sector $c$ at time $t$ let the sector size be denoted by $Z_{\text {ect }}$. $Z_{\text {ect }}$ can be measured as the sectoral (gross) output value $Y_{\text {ect }}$, as physically measured $\mathrm{CO}_{2}$ emissions $E_{\text {ect }}$ or, alternatively, as physically measured (gross) energy use (or in general other suitable indicators). Then the sector share in the entire economy can be defined as:

$$
\begin{equation*}
\frac{Z_{e c t}}{\sum_{c} Z_{e c t}}=f\left(\frac{K_{e c(t-1)}}{L_{e c(t-1)}}, \frac{M_{e c(t-1)}}{Y_{e c(t-1)}}, \sigma_{e c}, \theta_{t}, \varepsilon_{e c t}\right) \tag{1}
\end{equation*}
$$

with $\sum_{c} Z_{\text {ect }}$ indicating the sum of the sizes of all sectors $c$ in economy $e$ at time $t$, and $f(\ldots)$ representing a function of the arguments explained in the following paragraphs. Expecting a time lag between changes in the determinants on the right hand side and their effect on the left hand side, for the time being, let us assume one-period time lags denoted by $(t-1)$.
$K_{e c(t-1)}$ is the value of the sectoral capital stock and $L_{e c(t-1)}$ the physically measured ${ }^{4}$ sectoral labor input. The capital-to-labor ratio indicates capital intensity and indirectly the technology intensity of production (given that capital embodies technologies). It is ex ante unclear whether a higher capital intensity is associated with a smaller or larger sector share, because capital/technology and labor can be substitutes or complements.
$M_{e c(t-1)}$ denotes the total value of intermediate goods imports from the rest of the world. The import intensity $\frac{M_{e c(t-1)}}{Y_{e c(t-1)}}$ indicates the strength of international (trade) connections. Again, it is ex ante unclear whether a higher import intensity is associated with a smaller or larger sector share. This relation is in the spotlight of the analysis and will be explained in detail in the following paragraphs.
$\sigma_{e c}$ captures any other time-invariant economy- and sector-specific determinants within the cross-section, for example, sectoral productivity growth or the economy-wide infrastructure. $\theta_{t}$ captures any time-variant determinants that jointly affect all economies and sectors in the same way in each time period $t$, for example an oil price shock or a pandemic shock. $\varepsilon_{\text {ect }}$ captures any remaining unexplained random influences (noise).

## Sectoral two-economy model:

Now we are looking at dyadic trade connections between specific sectors in specific countries and compare the two trading partners in terms of their sectoral structures and the determinants of these connections. For this purpose, let us label source countries of trade as $s$, source sectors as $i$, recipient countries of trade as $r$ and recipient sectors as $j$. From this viewpoint and with this notation, our previous model is generalized to:

$$
\begin{equation*}
d z_{s r j t}=f\left(d k_{s r j(t-1)}, m_{s r j(t-1)}, \sigma_{s r j}, \theta_{t}, \varepsilon_{s r j t}\right) \tag{2}
\end{equation*}
$$

with $d z_{s r j t}=\left|\left(\frac{Z_{r j t}}{\sum_{j} Z_{r j t}}-\frac{Z_{s j t}}{\sum_{j} Z_{s j t}}\right) / \frac{Z_{s j t}}{\sum_{j} Z_{s j t}}\right|=\left|\frac{Z_{r j t}}{\sum_{j} Z_{r j t}} / \frac{Z_{s j t}}{\sum_{j} Z_{s j t}}-1\right|$ representing the relative distance (the absolute normalized difference with a positive sign) between the (output, $\mathrm{CO}_{2}$ or energy) shares of the same sector $j$ in the two countries $s$ and $r$ connected via trade, where $i=j$ is suppressed for simplicity. The division by $\frac{Z_{s j t}}{\sum_{j} Z_{s j t}}$ renders $d z_{s r j t}$ independent of the sector size, i.e., small and large sectors are weighted equally.

Similarly, $d k_{s r j(t-1)}=\left|\left(\frac{K_{r j(t-1)}}{L_{r j(t-1)}}-\frac{K_{s j(t-1)}}{L_{s j(t-1)}}\right) / \frac{K_{s j(t-1)}}{L_{s j(t-1)}}\right|=\left|\frac{K_{r j(t-1)}}{L_{r j(t-1)}} / \frac{K_{s j(t-1)}}{L_{s j(t-1)}}-1\right|$ represents the relative distance between the capital intensities in the sector $j$ (with $i=j$ ) of the two trading partners.

[^2]International trade is generalized to a bilateral, bisectoral sirj-relation. To keep the model tractable, we sum up over source sectors $i$ to obtain a bilateral trade relation with intermediate goods imports of sector $j$ in $r$ from all sectors of $s$. Hence, $m_{s r j(t-1)}=$ $\frac{\sum_{i} M_{s i r j(t-1)}}{Y_{r j(t-1)}}$ is the modified central trade measure under scrutiny.

Referring to the recipient country $r$ and sector $j$, the index of the time-invariant determinants is rewritten as $\sigma_{r j}$. Whereas the time-variant effects stay $\theta_{t}$, the error term now reads $\varepsilon_{s r j t}$, which completes the model setup.

## Testable hypotheses on trade and structural change:

There are basically two opposite possible approaches to the explanation of structural change and structural con-/divergence in the context of international trade.

The first approach refers to the classic Ricardian and Heckscher-Ohlin trade theories. Countries specialize in the goods and hence sectors, for which they have a productivitybased comparative advantage or for which they have relatively abundant endowments with the required production factors. In this framework, sector shares and trade intensities may reflect sector-specific productivities (Eaton \& Kortum, 2002). Induced factor- and sector-specific directed technological change (Acemoglu, 2002, 2010) may reinforce the heterogeneity of economic production depending on country-specific factor endowments, policies affecting sectors in different ways and other economic conditions. $5^{5}$ The New Economic Geography popularized by Krugman describes the agglomeration of economic activities. Local knowledge spillovers and linkages with customers and suppliers support the emergence of local specialization and clustering (Midelfart et al., 2003 Crespo \& Fontoura, 2007). It follows from this theory that over time, countries shift their production towards different sectors. This implies for structural change that countries' sectoral structures diverge, i.e., become more different over time. Intermediate goods imports ( $M$ ) and capital ( $K$ ) accumulation are expected to enhance this effect. In this context, capital reflects technologies, knowledge and absorptive capacity (with respect to the adoption of technologies and knowledge). In terms of the previously defined model, (Equation 2), the resulting hypothesis reads:

H1: International trade fosters structural divergence, i.e., $\frac{\partial\left(d z_{s r j t}\right)}{\partial\left(m_{s r j}(t-1)\right)}>0$.

[^3]H1 implies that the sectoral distances become larger. In a Ricardian world with full specialization, in each economy, some or all but one sector shares will become zero, i.e., $\frac{Z_{\text {ect }}}{\sum_{c} Z_{\text {ect }}}=0$ and thus the sectoral differences will diverge to the share of the sector of specialization, i.e., $d z_{s r j t}=\max \left\{\frac{Z_{s j t}}{\sum_{i} Z_{s j t}}, \frac{Z_{s r j t}}{\sum_{j} Z_{r j t}}\right\}$, where in practice both sector shares may become zero (no specialization in this sector among these two particular countries) and hence $d z_{s r j t}=0$.

The second approach refers to international technology (knowledge) diffusion in the course of globalization with international trade and economic development. Accordingly, over time countries' sectoral technologies and hence productivities converge, i.e., become more similar. Additionally, inter-industry trade supports the emergence of similar sectoral structures across trading partners, because it replaces the exchange of different goods produced in different sectors by trade in varieties of the same good within the same sector (Midelfart et al. 2003). This implies for structural change that countries' sectoral structures have the tendency to converge, i.e., become more similar over time. Again, intermediate goods imports $(M)$ and capital $(K)$ accumulation are expected to enhance this effect. Accordingly, the resulting hypothesis reads:

H2: International trade fosters structural convergence, i.e., $\frac{\partial\left(d z_{s r j t}\right)}{\partial\left(m_{s r j}(t-1)\right)}<0$.

H2 implies that the sectoral distances become smaller. In the theoretical long-run equilibrium of a fully integrated world economy, it is $\frac{Z_{s j t}}{\sum_{j} Z_{s j t}}=\frac{Z_{r j t}}{\sum_{j} Z_{r j t}} \forall(s, r, j)$ and thus $d z_{s r j t}=0$.

## 3 Data

In this section, we describe the data source and the aggregation of the panel data in terms of countries and sectors.

## Data source and setup:

Besides using the newest 2016 release of the large dataset WIOD (World Input-Output Database $\sqrt{6}_{6}^{6}$, we deploy the 2013 release for comparison $\sqrt[7]{ }$ We combine the World InputOutput Tables containing bilateral, bisectoral ${ }^{8}$ trade (in mill. 2010-US- $\$$, see below) data

[^4]with the Socio Economic Accounts containing sectoral (gross) outputs (in mill. 2010-US\$), labor (in 1000 employment units) and capital (in mill. 2010-US-\$) data and with the environmental accounts (the 2019 release 9 for the WIOD 2016) providing sectoral $\mathrm{CO}_{2}$ emissions (in 1000 tonnes) and sectoral energy use (in terrajoule) data. Following the model setup of the previous section, we sum up all intermediate good imports entering each sector across their sectors of origin, while keeping source-destination country dyads.

Monetary values expressed in 2010-US-\$ are measured in constant prices of the base year 2010. They are created by applying the corresponding deflator ${ }^{10}$ and, in the case of output and capital, by converting the national currency values to US-\$ with the corresponding exchange rate contained in the WIOD. $\mathrm{CO}_{2}$ emissions refer to direct emissions caused by fossil fuel-based energy use and process emissions released within the corresponding sector (excluding indirect emissions embodied in intermediate inputs). This allows us to study the change in production technologies in each sector. The alternative measure, (gross) energy use, refers to the total direct energy input (consumption) including electricity consumption in each sector.

We restrict the numerical setup to data sourced from WIOD ${ }^{11}$ to keep it as consistent as possible in terms of the sector definitions and accounting methods and to keep the numerical requirements tractable. In the time dimension, where $t$ denotes years, the 2013 release covers the time frame 1995 until 2009; the 2016 release covers the years 2000 until 2014. In the cross-section, our North-South setup includes 31 industrialized countries (OECD, North) in WIOD 2013 and 34 industrialized countries in WIOD 2016 versus 9 emerging countries (South) in both samples ${ }^{122}$ Depending on the available sectors in the original data source, we aggregate the sectors to 26 sectors $f$ (equivalently $i$ or $j$ ) in WIOD 2013 and 36 sectors in WIOD 2016 ${ }^{[13}$ Appendix C provides detailed sector

[^5]lists and mappings. This results in over 140 thousand observations in the North-South sample and about 870 thousand observations in the full sample of WIOD 2016, over 95 thousand observations in the North-South sample and over 520 thousand observations in the full sample of WIOD 2013. The full sample combines the emerging and industrialized countries to 40 economies (countries) $e$ in WIOD 2013 and 43 economies in WIOD 2016.

In the full sample, each country exports to each country, i.e., all countries are once source $s$ and once recipient $r$, while in the North-South setup, the industrialized (OECD) countries $s$ export to the emerging countries $r$.

## Descriptive statistics:

Figures 1 and 2 draw on the WIOD 2013 and 2016. They illustrate sectoral developments, computed as averages across the countries with each country group (emerging and industrialized countries or in short South and North). The sectoral developments refer to direct $\mathrm{CO}_{2}$ emissions or (gross) output shares of each sector in the total $\mathrm{CO}_{2}$ emissions or (gross) output of the corresponding country. Each single dot depict one observation, the solid (for WIOD 2013) or dashed (for WIOD 2016) lines depict averages, and the shaded areas indicated $95 \%$ confidence intervals. The investigation of the descriptive statistics reveals sectoral developments, including South-North con-/divergence, that suggest a detailed econometric exploration of their drivers.

Figures 1 and 2 depict selected sectors. In the energy sector (electricity, gas, water, steam and air conditioning supply, Figure 1 and 1b), the emerging countries (in blue) exhibit larger shares than the industrialized countries (in red), both, in terms of average output and $\mathrm{CO}_{2}$ shares. While at the end of the time frame, the output shares reveal a convergence tendency, the $\mathrm{CO}_{2}$ shares show a divergence tendency. Whereas the output shares move around $3 \%$, the $\mathrm{CO}_{2}$ shares exceed $40 \%$ in the emerging countries, which points to the high $\mathrm{CO}_{2}$ intensity of the energy sector.

In the energy-intensive chemicals sector (Figure 1 c and 1d), the sector shares have similar sizes in terms of output as in the energy sector and are again larger in the South. On the contrary, $\mathrm{CO}_{2}$ shares are an order of magnitude lower than in the energy sector. The Southern $\mathrm{CO}_{2}$ shares converge to those of the North.

[^6]Figure 1
Average sector shares in industrialized and emerging countries over time

Source: Own illustrations based on data taken from the WIOD 2013 and 2016 releases.

Figure 2
Average sector shares in industrialized and emerging countries over time

Source: Own illustrations based on data taken from the WIOD 2013 and 2016 releases.

Compared with the energy-intensive chemical sector, the $\mathrm{CO}_{2}$ share of machinery (Figure 1 e and 1 f ) is another order of magnitude lower (about $0.2 \%$ ). The output and $\mathrm{CO}_{2}$ machinery sector shares of the South and the North are nearly identical and change little over time.

In the land transport sector (Figure 2a and 2b), the South exhibits larger output shares than the North, but smaller $\mathrm{CO}_{2}$ shares (with a slightly increasing trend in both regions), which indicates an advantage of the South with regard to the $\mathrm{CO}_{2}$ emissions intensity.

In the construction sector (Figure 2 c and 2 d ), the emerging countries overtake the industrialized countries in terms of output shares, while the opposite occurs in terms of $\mathrm{CO}_{2}$ shares. This indicates significant $\mathrm{CO}_{2}$ emissions reductions in the South, although the Southern $\mathrm{CO}_{2}$ share exhibits a slightly increasing trend.

In agriculture (Figure 2 e and 2 f ), clearly, the Southern output shares exceed the Northern ones more than the $\mathrm{CO}_{2}$ shares, which indicates less $\mathrm{CO}_{2}$ emissions-intensive agricultural production in the South than in the North. Mostly the Southern output shares, but also the $\mathrm{CO}_{2}$ shares, converge to the Northern ones over time.

The next section will explore possible drivers of these sectoral developments (in the South relative to the North) in an econometric analysis. Appendix A. 1 provides summary statistics of the economic indicators in the different data samples as they appear in the econometric analysis. Appendix A. 2 uses the full sample to present all available data. It shows the correlations of the indicators appearing in one regression among each other in the upper right part. Accordingly, all correlations are low, i.e., within $\pm 0.2$. The lower left part illustrates the relation of the correlation partners by scatter-plotting each indicator as a function of its partner. The red lines sketch the non-linear relation between the correlation partners by using a non-parametric smoothing algorithm. They indicate moderate relations between the regressors and the dependent variable of the econometric model presented below. The histograms on the diagonal of the same figures depict the distributions (the density of observations covering an area with the size one) of the indicators. Accordingly, most of the logarithmic observations are located around zero.

## 4 Econometrics

This section first describes the econometric approach and the test procedures to implement it in the appropriate way; it then presents the regression results.

## Econometric approach:

To write out Equation 2 explicitly, we assume a multiplicative model, take natural logarithms on both sides and rearrange terms. To identify the joint effect of a higher import intensity and a higher capital-to-labor ratio, we add their multiplicative interaction.

$$
\begin{align*}
\ln \left(d z_{s r j t}\right)= & \alpha \cdot \ln \left(m_{s r j(t-1)}\right)+\beta \cdot \ln \left(d k_{s r j(t-1)}\right)+\gamma \cdot \ln \left(m_{s r j(t-1)}\right) \cdot \ln \left(d k_{s r j(t-1)}\right) \\
& +\delta \cdot \sigma_{s r j}+\eta \cdot \theta_{t}+\varepsilon_{s r j t} \tag{3}
\end{align*}
$$

with the relative distance between the sector shares of the source and the recipient, $d z_{s r j t}=$ $\left|\frac{Z_{r j t}}{\sum_{j} Z_{r j t}} / \frac{Z_{s j t}}{\sum_{j} Z_{s j t}}-1\right|$; the sectoral import intensity, $m_{s r j(t-1)}=\frac{\sum_{i} M_{s i r j(t-1)}}{Y_{r j(t-1)}}$, which is in the spotlight of the analysis; and the relative distance between the sectoral capital-to-labor ratios of the source and the recipient, $d k_{s r j(t-1)}=\left|\frac{K_{r j(t-1)}}{L_{r j(t-1)}} / \frac{K_{s j(t-1)}}{L_{s j(t-1)}}-1\right|$. The interaction term $\ln \left(d k_{\operatorname{srj}(t-1)}\right) \cdot \ln \left(m_{\operatorname{srj}(t-1)}\right)$ is included in the main regressions but left out in a robustness check.

These indicators are all constructed by using the WIOD. While we restrict the explicit inclusion of economic indicators to those with direct economic relevance and being covered by the WIOD with the required high bilateral and bisectoral resolution, we deploy a very large number of fixed-effects, which exploits the technical (computational) limits of the estimation procedure.

To model triadic fixed-effects, the binary variables $\sigma_{s r j}$ and $\theta_{t}$ take the value of one for each bilateral sectoral trade relation and each year. The index srj combines source country $s$, recipient country $r$ and recipient sector $j$ characteristics, while $t$ indicates the individual time dimension. The joint use of $\sigma_{s r j}$ and $\theta_{t}$ leads to a two-way fixed effects model, which in short will be denoted by $\operatorname{srj} \& t$. Alternatively, either $\sigma_{s r j}$ or $\theta_{t}$ can be used to implement single fixed-effects models with cross-sectional fixed-effects, in short, $s r j$, or time-fixed effects, in short, $t$.
$\alpha, \beta, \gamma, \delta$ and $\eta$ are to be estimated, while $\varepsilon_{s r j t}$ is the error term. If Hypothesis H1 holds, then $\alpha>0($ and $\beta>0)$, if H2 holds, then $\alpha<0($ and $\beta<0)$.

## Test procedures:

We carry out the following standard test procedures. We check that the correlations among regressors are sufficiently low (i.e., within $\pm 0.2$, see Appendix A. 1 and the end of the previous section) to avoid multicollinearity. The standard $F$-tests for the null hypothesis of all estimated coefficients jointly being zero are reported for each regression (see the last row in Tables 1 to 4). In the estimations yielding significant results, the $F$-statistics are (very) high. The $R^{2}$ values are overall low, which hinges on the model specification with economic indicators specified as shares, ratios or intensities, measured in relative and absolute terms.

Additionally, we carry out several test procedures for panel data. We apply Fisher type Augmented Dickey-Fuller unit root tests for panel data (Dickey \& Fuller, 1979; Im et al. 2003) to ensure that all data are stationary. Consequentially, we test all dependent and independent variables in all datasets (WIOD 2016 and 2013) and all subsamples (North-South and full sample) separately. We find that the unit-root null hypothesis is always clearly rejected in favor of stationarity (at the 0.00001 confidence level).

The standard Hausman test for fixed- versus random-effects clearly rejects the null hypothesis of consistent random-effects in all specifications; therefore, we restrict our analysis to the use of fixed-effects (dummy variables).

We apply $F$ - and $L M{ }^{14}$ tests evaluating different types of fixed-effects against the null hypothesis of a pooled regression or reduced dimensionality (i.e., a reduced number) of fixed-effects. Appendix A. 3 presents the tests results. For all specifications, the $F$ and $L M$-tests clearly reject the null hypothesis of all fixed-effects jointly being zero, i.e., the pooled regression. Similarly, the $F$ - and $L M$-tests clearly reject the null hypothesis of fixed-effects with reduced dimensionality, i.e., cross-sectional fixed-effects plus time fixedeffects (two-way fixed-effects, $s r j \& t$ ) are preferable over cross-sectional fixed-effects only (srj) or time fixed-effects only $(t)$.

For the choice between cross-sectional or time fixed-effects versus two-way fixed-effects, however, Kropko \& Kubinec (2020) recommend the choice of a single type of fixed-effects to enable a clear-cut interpretation of the estimation results with respect to variant and invariant effects in the time and the cross-sectional dimension instead of generating a mixture of both, which is difficult to interpret. Therefore, we use and compare the three fixed-effects specifications ( $s r j, t$ and $s r j \& t$ ). When using cross-sectional fixed-effects, the variation remaining in the data is generated within the time dimension across

[^7]years. When using time fixed-effects, on the opposite, the variation remaining in the data is generated in the cross-sectional dimension via differences between countries and sectors that may be interpreted as a snapshot of the current situation or as long-term (equilibrium) effects. When using two-way fixed-effects, both types of variation overlap similar to a pooled regression (cf. Kropko \& Kubinec, 2020).

## Regression results:

Tables 1 to 4 present the main panel estimation results. We report heteroscedasticityand serial correlation-robust standard errors (Arellano, 1987) clustered at the srj-level throughout the regression analysis.

Based on the WIOD 2016, Table 1 uses output shares as the dependent variable. The statistically significant and negative coefficients of the important intensity in all columns of Table 1 unequivocally confirm H 2 stating structural convergence induced by international trade. The effect of the capital-to-labor intensity on structural change is significant in the full sample estimations with fixed-effects in the cross section ( $s r j$ ) and in the cross-section plus time $(\operatorname{srj} \& t)$ only. In these significant cases, the coefficients also confirm H 2 stating structural convergence induced by more capital-intensive production.

In Table 1, the interaction term's coefficients are significant and negative supporting H2 in all full sample estimations and in the North-South sample estimation with time ( $t$ ) fixed-effects, but insignificant in the remaining two North-South sample results. Accordingly, a higher import intensity and a higher capital intensity jointly enhance structural convergence.

Table 2 shows the same estimations with output shares as the dependent variable based on WIOD 2013. WIOD 2013 provides a smaller number of observations than WIOD 2016, which potentially reduces the statistical significance of the results. Accordingly, the import intensity's coefficient turns insignificant in the North-South sample with cross sectional fixed-effects ( $s r j$ ) and weakly significant and negative with two-way fixed-effects $(s r j \& t)$. The import intensity's coefficient turns significant and positive in the full sample with cross-sectional fixed-effects $s r j$ supporting H1 stating structural divergence. Nonetheless, the majority of the estimates ( $t$ with the North-South sample, $t$ and $s r j \& t$ with the full sample) is in favor of H2, i.e., structural convergence as before. The effect of the capital-to-labor ratio is significant with time $(t)$ fixed-effects only. Here it is positive in favor of H 1 too.

Table 1
Panel regression results with output shares using WIOD 2016

| Fixed-effects | Dep. var.: relative distance between sectoral output shares $\ln \left(d z_{s r j t}\right)$ |  |  |  |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: |

Table 3 replaces the output shares used as the dependent variable by $\mathrm{CO}_{2}$ shares (including emissions from fossil fuel use and process emissions) drawing on the WIOD 2016. Similar to the results with output shares and the WIOD 2013, the sign of the estimates depends on the choice of the fixed-effects. The cross-sectional fixed-effects (srj) allow for variation in time and exhibit a positive effect of the import intensity on structural change, i.e., divergence as expressed by H1. Time fixed-effects $(t)$, on the contrary, allow for variation in the cross-section and result in a positive effect supporting structural convergence as expressed by H2. The combination of both types of fixed-effects ( $s r j \& t$ ) and hence both opposing effects, not surprisingly, results in insignificant estimates. These observations apply to the North-South and the full sample.

In contrast to these estimates for trade, the capital-to-labor ratio exhibits a significant and negative effect supporting structural convergence with cross-sectional fixed-effects $(s r j)$ in the North-South sample, but a significant and positive effect supporting divergence with time fixed-effects $(t)$ in the full sample. It exhibits insignificant effects in the remaining cases. Nonetheless, the joint effect is always (weakly) significant and negative, supporting convergence, in the North-South sample.

Table 4 deploys $\mathrm{CO}_{2}$ shares as the dependent variable using the WIOD 2013. The results are similar to those deploying output shares using the WIOD 2016 presented in Table 1. The estimated coefficients of the import intensity are significant and negative in all estimations supporting H2 stating structural convergence. The effect of the capital-to-labor-ratio is, however, always insignificant. The joint effect of the import intensity and capital-to-labor-ratio expressed by the interaction term is always negative, but statistically significant in the specifications with time $(t)$ fixed-effects only.

All estimated coefficients represent elasticities, describing the impact of relative changes in a driver of structural change on relative changes in the (absolute) difference between the sector shares of the recipient and source country of international trade. The estimated (absolute) magnitudes of these elasticities vary between 0.02 and 0.05 among the statistically significant coefficients of the capital-to-labor-ratio. The (absolute) magnitudes of the interaction terms are about an order of magnitude smaller. The variation of the (absolute) magnitudes of the coefficients of the import intensity is substantial; the magnitudes vary between about 0.004 and 0.116 .

## 5 Discussion

This section interprets and compares the regression results, particularly those of the main panel regressions presented in the previous section, those of alternative robustness checks and those of supplementary sectoral estimates.

## Main regression results:

Basically, the results promote the view that international trade supports the international convergence of sectoral structures via the spread of knowledge, technologies, and so forth, such that countries' sectoral structures become more similar. Likewise, more intensive utilization of capital and embodied technologies supports the international convergence of sectoral structures. Using the WIOD 2016 sample and output value shares as the dependent variable, this result holds unequivocally and significantly.

For the WIOD 2013 sample period from 1995 to 2009, however, the results provide indication that over time, international trade enhanced the international divergence of sectoral output structures. This means that, in accordance with the classical Ricardian trade theory, in the world economy, countries specialized in the production of different goods. Similarly, in the global (long-term) cross-section, more intensive capital use seems to foster sectoral divergence of output structures.

When considering $\mathrm{CO}_{2}$ shares taken from the WIOD 2013 as the dependent variable, on the contrary, the results clearly confirm the previous finding that trade fosters structural convergence.

For the later WIOD 2016 sample period from 2000 to 2014, however, the results point to a possible regime change. From a global and a North-South perspective, the results indicate international divergence of sectoral structures occurring via Ricardian specialization in more or less $\mathrm{CO}_{2}$-intensive production. This result points to international outsourcing of $\mathrm{CO}_{2}$-intensive production to emerging economies or so-called carbon leakage.

## Robustness check results:

The following robustness checks exclude the interaction terms used so far, explore different time lags of regressors and replace $\mathrm{CO}_{2}$ emissions by energy use to construct the dependent variable. The robustness checks overall confirm the main panel regression results.

1. Exclusion of the interaction term: The results for WIOD 2016 are presented in Appendix B.1. The estimated coefficients of the import intensity are very robust to the
exclusion of the interaction term of the import intensity with the capital-to-labor-ratio. The coefficients of the capital-to-labor-ratio, on the contrary, experience changes in the significance levels and signs; particularly, most coefficients turn statistically significant and positive, supporting structural divergence (H1). This result nevertheless fits to economic theory and intuition: More intensive capital use itself tends to result in increasing specialization in the activities that can be performed best with this capital and its embodied technologies. Once, new goods, knowledge, technologies etc. arrive from abroad, the capital will incorporate technological improvements such that production will become more similar to the production at the source of the goods, knowledge and technologies. Thus, international trade appears to be a prerequisite for international structural convergence (H1), while capital accumulation supports this trade-driven mechanisms. This is reflected by the (if statistically significant) always negative interaction terms.
2. Different time lags of regressors: The results for WIOD 2016 with the time (year) lags $t-2$ and $t-3$ instead of $t-1$ for all regressors are presented in Appendix B.2. While some significance levels change, the results are qualitatively and quantitatively hardly affected. As a notable exception, in the full sample with cross-sectional fixed-effects ( $s r j$ ), $t-3$ lags and output shares as the dependent variable, presented in Table B4, the effect of imports becomes significant and positive. Likewise, in the North-South and full sample with two-way fixed-effects $(\operatorname{srj} \& t), t-2$ or $t-3$ lags and $\mathrm{CO}_{2}$ shares as the dependent variable, presented in Tables B5 and B6, the positive effect of imports becomes significant.
3. Energy shares as the dependent variable: In this robustness check presented in Appendix B.3, we replace the $\mathrm{CO}_{2}$ emissions shares by (gross) energy input shares. Compared with $\mathrm{CO}_{2}$ emissions, the (gross) energy use includes electricity and other non- $\mathrm{CO}_{2}$-emitting energy inputs. In both samples, WIOD 2013 and 2016, all statistically significant coefficients of the import intensity and the interaction with the capital-to-labor ratio have a negative sign, supporting structural convergence (H2). The coefficients of the capital-to-labor ratio are always insignificant. Particularly, in WIOD 2016, the import intensity has a significant and negative effect on structural change with cross-sectional $(s r j)$ or time $(t)$ fixed-effects, but not with two-way fixed-effects ( $\operatorname{srj} \& t$ ); in WIOD 2013, the import intensity has a significant and negative effect with time ( $t$ ) fixed-effects and in the full sample also a weakly significant and negative effect with two-way fixed-effects $(\operatorname{srj} \& t)$. This means, regarding the impact of imports estimated with WIOD 2013, the energy share results are in line with the previous $\mathrm{CO}_{2}$ share and output share results (except the single significantly positive effect of the import intensity when using output
shares). With WIOD 2016, however, the energy share results confirm the previous finding of convergence (H2) driven by imports with output shares, but do not confirm the previous finding of divergence ( H 1 ) driven by imports obtained with $\mathrm{CO}_{2}$ shares and cross-section fixed-effects ( $s r j$ ).

## Sectoral regression results:

To understand how structural change actually occurs, we need to look at the sectoral level. To this end, we carry out the panel regressions separately for each sector $j$. As before, we use cross-sectional $(s r)$, time $(t)$ or two-way ( $s r \& t$ ) fixed-effects based on WIOD 2013 or 2016. Appendix B. 4 presents selected results of the sector-specific estimations. In each table, all available sectors are included and ordered by the $\mathrm{CO}_{2}$ intensities of the trade recipient countries $r$. The left columns of the tables show the sector shares in the trade recipient countries $r$ at the beginning and the end of the sample period in terms of emissions or output. This reveals, whether the sectors were shrinking or expanding during the sample period.

Table B9, for example, indicates that the energy sector is the most $\mathrm{CO}_{2}$-intensive sector, slightly expanded between the years 2000 and 2014 and exhibits a significantly negative effect of the imports intensity (structural convergence), but a significantly positive effect (structural divergence) of the capital-to-labor ratio and the interaction of imports with capital on the relative distance of output shares. The number of observations in this sector is 25,284 , the number of fixed-effects is 1,806 . Whereas the $R^{2}$ is low, the $F$-statistic for the null hypothesis of all estimated coefficients jointly being zero is high, clearly rejecting the null hypothesis.

The sectoral panel regression results overall confirm the cross-sectoral panel regression results. The estimates with WIOD 2016 and output value shares as the dependent variable overall confirm the hypothesis of structural convergence (H2) driven by trade. While in the estimations with cross-sectional fixed-effects, about half of the coefficients of imports are statistically significant, most of them with a negative sign, in the specification with time fixed-effects most of them are significant, all with a negative sign.

In accordance with the previous cross-sectoral results, in the WIOD 2016 sample, the use of $\mathrm{CO}_{2}$ shares as the dependent variable leads to mostly positive coefficients of the the import intensity among the relatively small number of statistically significant results, when cross-sectional fixed-effects (sr) are included. Based on the WIOD 2013 sample, on the contrary, the significant estimates of the effect of imports are mostly negative in
favor of the convergence hypothesis (H2). This result supports the previous finding of structural divergence (H1), i.e., the specialization in more or less $\mathrm{CO}_{2}$-intensive activities starting around the year 2000. When using time ( $t$ fixed-effects), on the contrary, more coefficients of imports become statistically significant and all of them are negative in favor of the convergence hypothesis (H2) as before.

There are less significant estimates of the effect of the capital-to-labor ratio than of the import intensity. Although negative signs prevail for capital, the estimated signs are mixed. The estimates of the interaction effect of imports and capital show a similar picture as the estimates of the capital effects.

## 6 Conclusion

The classical Ricardian trade theory predicts differences between economic structures of countries engaged in international trade, because each country specializes in specific sectors (goods) according to comparative advantages. Our results, however, basically oppose this view. Instead, most results show that international trade leads to increasing similarity of economic structures. This mechanism can be driven by the spread of knowledge, technologies, tastes, habits, and so forth, during the course of globalization. This finding holds when sector shares are measured using output value shares or energy input shares and, for the data sample covering the time period before the turn of the millennium, it holds when using $\mathrm{CO}_{2}$ emissions shares. Running panel regressions for the available sectors separately confirms these cross-sectoral panel regression results.

Because advanced technologies need to be embodied in capital, this mechanism is enhanced when imports are accompanied by more intensive capital use, which is visible in the results. This means, the joint effect of import- and capital-intensive production enhances sectoral convergence, whereas the sole effect of a higher capital-to-labor ratio on structural convergence appears to be ambiguous, because capital use without sufficient imports may embody old-fashioned technologies. Capital can thus be called an enhancer of structural convergence.

The finding of structural convergence driven by international trade basically means good news for climate and energy policy: over a sufficiently long time horizon, energy- and $\mathrm{CO}_{2}$ emissions-saving inter-sectoral structural change in industrialized countries automatically spills over to emerging countries via international trade. The results, however, also provide indication for increasing international specialization in more or less $\mathrm{CO}_{2}$-intensive production starting at the turn of the millennium. This outcome, too, is confirmed when
running panel regressions for the available sectors separately. Among other possible reasons, this outcome might be driven by the international relocation of $\mathrm{CO}_{2}$-intensive production to emerging economies, which might be fostered by climate policy measures in industrialized countries, so-called carbon leakage. However, this outcome does not hold when replacing $\mathrm{CO}_{2}$ emissions shares by energy input shares. Energy input shares refer to gross energy use including electricity and non-emissions-relevant energy sources. They are affected by (total factor) productivity gains and energy-specific productivity gains. $\mathrm{CO}_{2}$ emissions shares, on the contrary, capture the emissions-intensity and decarbonization of energy supply and industrial production.

Nonetheless, this insight is somewhat alarming for climate policy makers, because it implies that more stringent climate policy in industrialized countries may decrease direct $\mathrm{CO}_{2}$ emissions in particular sectors of industrialized countries but increase them in the same sectors of emerging (or developing) countries, resulting in structural divergence. As long as no global climate policy solution is in place, this mechanism weakens the effectiveness of unilateral climate policy in the globalized world economy. Therefore, in addition to the potentially productivity-enhancing and energy-saving effects of international trade Cole, 2006, Perkins \& Neumayer, 2009; Hübler \& Glas, 2014), policies should directly strengthen the international transfer of environmental-friendly and particularly $\mathrm{CO}_{2}$ emissions-saving technologies. The ultimate goal would be a global climate policy solution that avoids carbon leakage effects.

These empirical results should, however, be treated with caution, especially because some outcomes depend on the time frame (data sample) and the choice of the exploited variation in the data (cross-section, time fixed-effects or both). Future research may study further drivers of structural change that may independently or in connection with international trade foster structural divergence or convergence. It may also study selected countries or sectors in detail. It is open to question, whether the international specialization in more or less $\mathrm{CO}_{2}$-intensive production that our analysis has indicated for this millennium, is a temporal statistical or negligible phenomenon or the beginning of a considerable long-term process.

## 7 Acknowledgment

We gratefully acknowledge financial support by the German Federal Ministry of Education and Research (BMBF, project ROCHADE, grant number: 01LA1828C). We thank the participants of the Rochade project meetings, particularly, Jan Steckel, Gabriel Fel-
bermayr and Marian Leimbach, for helpful comments. We thank Yoto Yotov for helpful discussions and Frank Pothen for a useful reference.

## A. 2 Correlations and distributions

Figure 3
Descriptive statistics with output shares using the WIOD 2016 full sample

Source: Own illustrations based on data taken from the WIOD 2016 release. The numbers in the upper right area are correlations between the two indicators named on the upper horizontal and right vertical axis of the depiction matrix. The lower left area illustrates the relation of the correlation partners by scatter-plotting the indicator named on the right vertical axis as a function of the indicator named on the upper horizontal axis. The red lines in the scatter-plots in the lower left area have been created by using a non-parametric algorithm based on generalized additive models with integrated smoothness estimation procedures as suggested by Wood (2011, 2004). The histograms on the diagonal depict the distributions (density of observations covering an area with the size one) of each indicator separately.

| WIOD 2016 | North-South | absent | $F$-test for two-way effects | srj | $s r j \& t$ | $50.502^{* * * * *}(d f=13 ; 133162)$ |
| WIOD 2016 | Full sample | absent | $F$-test for individual effects | pooled | srj | $52.984^{* * * * *}(d f=62386 ; 809345)$ |
| WIOD 2016 | Full sample | absent | $F$-test for two-way effects | pooled | $s r j \& t$ | $53.098^{* * * * *}(d f=62399 ; 809332)$ |
| WIOD 2016 | Full sample | absent | $F$-test for time effects | pooled | $t$ | $3178.550^{* * * * *}(d f=14 ; 871717)$ |
| WIOD 2016 | Full sample | absent | $F$-test for two-way effects | $t$ | $s r j \& t$ | $49.900^{* * * * *}(d f=62385 ; 809332)$ |
| WIOD 2016 | Full sample | absent | $F$-test for two-way effects | $s r j$ | $s r j \& t$ | $118.767^{* * * * *}(d f=13 ; 809332)$ |

Significance levels: ${ }^{*} p<0.1 ;^{* *} p<0.05 ;^{* * *} p<0.01 ;^{* * * *} p<0.005 ;^{* * * * *} p<0.001$. Independent variables are included with $t-1$ lags. $d f$ means degrees of freedom, where the first number is the difference of the $d f$ between $H 0$ and $H 1$, whereas the second number is the $d f$ in the model $H 1$. srj indicates the combined dimensions of fixed-effects for source country $s$, recipient country $r$ and recipient sector $j$ characteristics; $t$ denotes the dimension of the individual time fixed-effects; srj \& $t$ indicates the two-way fixed effects model. Alternative fixed-effects specifications (H1) are tested against a pooled or a fixed-effects specification with reduced dimensionality (a reduced number of fixed-effects) (H0).

Significance levels: ${ }^{*} p<0.1 ;^{* *} p<0.05 ;^{* * *} p<0.01 ;^{* * * *} p<0.005 ;^{* * * * *} p<0.001$. LM means
Lagrange Multiplier. Independent variables are included with $t-1$ lags. srj indicates the combined dimensions of fixed-effects for source country $s$, recipient country $r$ and recipient sector $j$ characteristics; $t$ denotes the dimension of the individual time fixed-effects; srj \& $t$ indicates the two-way fixed effects model. All alternative fixed-effects specifications (H1) are tested against a pooled specification (H0).

Table A6
$F$-tests for fixed-effects (H1) vs. pooled or restricted fix.-e. (H0), $\mathrm{CO}_{2}$ shares

## C WIOD sector mappings

Table C1
Sector mapping of the WIOD 2016 and 2013 datasets

| Sector |  | WIOD 2016 |  | Sector codes |  | WIOD 2013 |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| Trade | Non-trade | Definition | Aggregate | Trade | Non-trade | Definition | Aggregate |
| r1 | A01 | Crop and animal production. | A01-Agriculture | c1 | secAtB | Agriculture, Hunting, Forestry and Fishing | 1-Agriculture |
| r2 | $\mathrm{A}^{2} 2$ | Forestry and logging | A02-Forestry |  |  |  |  |
| r3 | A03 | Fishing and aquaculture | $\mathrm{A}^{03}$-Fisheries |  | - |  |  |
| r4 | B | Mining and quarrying | B-Mining | c2 | secC | Mining and Quarrying | B-Mining |
| r5 | $\mathrm{C}^{10-\mathrm{C} 12}$ | Man. food, beverages and tobacco | C10-C12-Food | c3 | sec 15t16 | Food, Beverages and Tobacco | C10-C12-Food |
| r6 | C13-C15 | Man. textiles, wearing apparel and leather products | C13-C15-Textile | ${ }^{4} 4$ | sec $17 \mathrm{t18}$ | Textiles and Textile Products | C13-C15-Textile |
|  | - | - |  | c5 | sec 19 | Leather, Leather and Footwear | C13-C15-Textile |
| r7 | C16 | Man. wood and of products of wood and cork, except furniture | C16-Wood | c6 | sec20 | Wood and Products of Wood and Cork | C16-Wood |
| r8 | C17 | Man. paper and paper products | C17-Paper | c7 | sec21t22 | Pulp, Paper, Paper , Printing and Publishing | C17-Paper |
| r9 | C18 | Printing and reproduction of recorded media | C18-Printing |  |  |  |  |
|  | C19 | Man. coke and refined petroleum products | C19-Refined Petr. | c8 | sec23 | Coke, Refined Petroleum and Nuclear Fuel | C19-Refined Petr. |
| r11 | C20 | Man. chemicals and chemical products | C20-Chemicals | c9 | sec 24 | Chemicals and Chemical Products | C20-Chemicals |
| ${ }_{\text {r12 }}$ | C21 | Man. basic pharmaceutical products | C21-Pharma. |  |  |  |  |
| r13 | C22 | Man. rubber and plastic products | C22-Rubber | ${ }^{10}$ | sec 25 | Rubber and Plastics | C22-Rubber |
| r14 | C23 | Man. other non-metallic mineral products | C23-Minerals | c11 | sec 26 | Other Non-Metallic Mineral | C23-Minerals |
| r15 | C24 | Man. basic metals | C24-Metal | c12 | sec27t28 | Basic Metals and Fabricated Metal | C24-Metal |
| r16 | C25 | Man. fabricated metal products | C25-Non machinery |  |  |  |  |
| r17 | C26 | Man. computer, electronic and optical products | C26-Computers | c13 | sec29 | Machinery, Nec | C26-Computers |
| r18 | C27 | Man. electrical equipment | C27-Electrical equip. | c14 | sec 30 t 33 | Electrical and Optical Equipment | C27-Electrical equip. |
| r19 | C28 | Man. machinery and equipment n.e.c. | C28-Machinery | - | - | - |  |
| r20 | C29 | Man. motor vehicles, trailers and semi-trailers | C29-Vehicles |  |  |  |  |
| r21 | C30 | Man. other transport equipment | C30-Transport equip. | c15 | sec 34435 | Transport Equipment | C30-Transport equip. |
| r22 | C31-C32 | Man. furniture; other manufacturing | C31-C32-Furniture |  |  |  |  |
| r23 | C33 | Repair and installation of machinery and equipment | C33-Repair | ${ }^{\text {c16 }}$ | sec36t37 | Manufacturing, Nec; Recycling | C33-Repair |
| ${ }_{\text {r24 }}$ | D35 | Electricity, gas, steam and air conditioning supply | D35-Energy | c17 | secE | Electricity, Gas and Water Supply | D35-Energy |
| r25 | E36 | Water collection, treatment and supply | E36-Water | - | - | - | - |
| ${ }_{\text {r } 26}$ | E37-E39 | Sewerage; waste collection, treatment and disposal activities | E37-E39-Waste |  |  |  |  |
| r27 | F | Construction | F-Construction | c18 | secF | Construction | F-Construction |
| r28 | G45 | Wholesale and retail trade of motor vehicles | G-Trade | c19 | sec50 | Sale, mainten. repair of motor vehicles | G-Trade |
| r29 | G46 | Wholesale trade, except of motor vehicles and motorcycles | G-Trade | c20 | sec51 | Wholesale trade, except of motor vehicles | G-Trade |
| r30 | G47 | Retail trade, except of motor vehicles and motorcycles | G-Trade | c21 | sec52 | Retail Trade, Except of Motor Vehicles | G-Trade |
| r31 | H49 | Land transport and transport via pipelines | H49-Land transport | c23 | sec60 | Inland Transport | H49-Land transport |

    3 http://www.wiod.org/home.

[^2]:    ${ }^{4}$ E.g., measured as the number of persons working in a sector.

[^3]:    ${ }^{5}$ Whereas technological change normally increases the sectoral productivity and hence the sectoral output, it can in- or decrease sectoral (factor) inputs (of labor, capital, energy or $\mathrm{CO}_{2}$ caused by fossil fuel inputs) depending on whether technological change is factor-augmenting or factor-saving.

[^4]:    ${ }_{6}^{6}$ http://www.wiod.org/home, Timmer et al. 2015,2016 .
    ${ }^{7}$ The WIOD 2013 and 2016 do not exactly match in terms of the sectoral definitions; therefore and to keep the number of observations computationally tractable, we deploy them separately.
    ${ }^{8}$ Bilateral, bisectoral means that international trade flows from any sector in any country to any sector

[^5]:    in any country.
    ${ }^{9}$ Corsatea et al. (2019)
    ${ }^{10}$ We apply the WIOD deflator containing price levels of intermediate inputs to discount trade values, price levels of (gross) output to deflate (gross) output values and price levels of (gross) value added to deflate capital values.
    ${ }^{11}$ This includes deflators and exchange rates.
    ${ }^{12}$ Emerging countries (South) in WIOD 2013 and 2016: "BRA" Brazil, "BGR" Bulgaria, "CHN" China Mainland, "MEX" Mexico, "RUS" Russia, "TWN" Taiwan, "ROU" Romania, "IND" India, "IDN" Indonesia.
    Industrialized countries (North) in WIOD 2013 and 2016: "AUS" Australia, "AUT" Austria, "BEL" Belgium, "CAN" Canada, "CYP" Cyprus, "CZE" Czechia, "DEU" Germany, "DNK" Denmark, "ESP" Spain, "EST" Estonia, "FIN" Finland, "FRA" France, "GBR" Great Britain, "GRC" Greece, "HUN" Hungary, "IRL" Ireland, "ITA" Italy, "JPN" Japan, "KOR" Republic of Korea, "LTU" Lithuania, "LUX" Luxembourg, "LVA" Latvia, "MLT" Malta, "NLD" The Netherlands, "POL" Poland, "PRT" Portugal, "SVK" Slovakia, "SVN" Slovenia, "SWE" Sweden, "TUR" Turkey, "USA" United States of America.
    Additional industrialized countries (North) in WIOD 2016: "CHE" Switzerland, "HRV" Croatia, "NOR" Norway.
    ${ }^{13}$ Sectors in WIOD 2013 and 2016: A01 Agriculture, B Mining, C10-C12 Food, C13-C15 Textile, C16 Wood, C17 Paper, C19 Refined Petr., C20 Chemicals, C22 Rubber, C23 Minerals, C24 Metal, C26

[^6]:    Computers, C27 Electrical equip., C30 Transport equip., C33 Repair, D35 Energy, F Construction, G Trade, H49 Land transport, H50 Water transport, H51 Air transport, H52 Warehousing, H53 Post, I Accommodation, JKLMN Private Services, OPQRS Public Services.
    Additional sectors in WIOD 2016: A02 Forestry, A03 Fisheries, C18 Printing, C21 Pharma., C25 Non machinery, C28 Machinery, C29 Vehicles, C31-C32 Furniture, E36 Water, E37-E39 Waste.
    The sectors T Household and U Household are discarded in both samples due to the absence of trade.

[^7]:    ${ }^{14}$ Lagrange Multiplier.
